

Task - 16: Incident Response & Security Breach Simulation

Internship Task – Elevate Labs

This task focused on understanding incident response processes by simulating a basic security incident. The objective was to identify suspicious activity, respond effectively, and document actions taken to restore systems to a secure state.

1. Incident Simulation

A basic security incident was simulated, such as repeated failed login attempts and unauthorized access. This helped in understanding how real-world security incidents begin.

2. Log Analysis

System and authentication logs were analyzed using Linux logs or Windows Event Viewer. Suspicious patterns such as multiple failed logins from the same source were identified.

3. Incident Classification

The incident was classified based on: - Attack type - Severity level - Potential impact

Proper classification helps in deciding response priority.

4. Containment Actions

Affected user accounts or systems were isolated to prevent further damage. Containment ensured the incident did not spread to other systems.

5. Eradication and Root Cause Fix

The root cause of the incident was identified and resolved. Actions included resetting credentials, fixing misconfigurations, and removing malicious access points.

6. System Recovery

Systems were restored to a secure operational state. Normal services were resumed after verification.

7. Incident Timeline Documentation

A detailed timeline of events and actions taken during the incident was documented for reference and analysis.

8. Preventive Recommendations

Recommendations included: - Enforcing strong authentication - Enabling account lockout policies - Continuous log monitoring - User security awareness training

Learning Outcome

Through this task, I gained practical knowledge of incident response handling. I learned how to detect, contain, eradicate, and recover from security incidents, and understood the importance of documentation and preventive measures.
